# The different regimes of QCD

Small values of  $\alpha_s$  (perturbation theory applies if there is a hard scale) can be compensated by large logarithmic enhancements.

DGLAP

strong ordering in  $k_T$ 

$$\sum (\alpha_s \ln Q^2)^n$$

BFKL

strong ordering in  $x$ 

$$\sum (\alpha_s \ln s)^n$$

When  $\sqrt{s}$  becomes very large, it is expected that a BFKL description is needed to get accurate predictions

## QCD in the perturbative Regge limit

The amplitude can be written as:

$$\mathcal{A} = \underbrace{\text{Diagram 1}}_{\sim s} + \left( \text{Diagram 2} + \text{Diagram 3} + \dots \right) + \left( \text{Diagram 4} + \dots \right) + \dots$$

$\sim s$ 
 $\sim s (\alpha_s \ln s)$ 
 $\sim s (\alpha_s \ln s)^2$

this can be put in the following form :

- Higher order corrections to BFKL kernel are known at NLL order (Lipatov Fadin; Camici, Ciafaloni), now for arbitrary impact parameter  $\alpha_S \sum_n (\alpha_S \ln s)^n$  resummation
- impact factors are known in some cases at NLL
  - $\gamma^* \rightarrow \gamma^*$  at  $t = 0$  (Bartels, Colferai, Gieseke, Kyrielleis, Qiao; Balitski, Chirilli)
  - forward jet production (Bartels, Colferai, Vacca; Caporale, Ivanov, Murdaca, Papa, Perri; Chachamis, Hentschinski, Madrigal, Sabio Vera)
  - inclusive production of a pair of hadrons separated by a large interval of rapidity (Ivanov, Papa)
  - $\gamma_L^* \rightarrow \rho_L$  in the forward limit (Ivanov, Kotsky, Papa)

## Mueller-Navelet jets

- Consider two jets (hadrons flying within a narrow cone) **separated by a large rapidity**, i.e. each of them almost fly in the direction of the hadron “close” to it, and with very similar transverse momenta
- in a pure LO collinear treatment, these two jets should be emitted **back to back** at leading order:  $\Delta\phi - \pi = 0$  ( $\Delta\phi = \phi_1 - \phi_2 =$  relative azimuthal angle) and  $k_{\perp 1} = k_{\perp 2}$ . There is no phase space for (untagged) emission between them

$k_T$ -factorized differential cross section

$$\frac{d\sigma}{d|\mathbf{k}_{J1}| d|\mathbf{k}_{J2}| dy_{J1} dy_{J2}} = \int d\phi_{J1} d\phi_{J2} \int d^2\mathbf{k}_1 d^2\mathbf{k}_2$$

$$\times \Phi(\mathbf{k}_{J1}, x_{J1}, -\mathbf{k}_1)$$

$$\times G(\mathbf{k}_1, \mathbf{k}_2, \hat{s})$$

$$\times \Phi(\mathbf{k}_{J2}, x_{J2}, \mathbf{k}_2)$$

$$\text{with } \Phi(\mathbf{k}_{J2}, x_{J2}, \mathbf{k}_2) = \int dx_2 f(x_2) V(\mathbf{k}_2, x_2) \quad f \equiv \text{PDF} \quad x_J = \frac{|\mathbf{k}_J|}{\sqrt{s}} e^{y_J}$$

LL BFKL

$$\sum (\alpha_s \ln s)^n$$

NLL BFKL

$$\sum (\alpha_s \ln s)^n + \alpha_s \sum (\alpha_s \ln s)^n$$

In the following we show results for

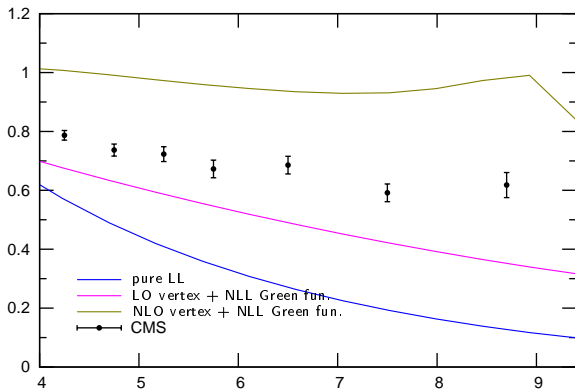

- $\sqrt{s} = 7 \text{ TeV}$
- $35 \text{ GeV} < |\mathbf{k}_{J1}|, |\mathbf{k}_{J2}| < 60 \text{ GeV}$
- $0 < |y_1|, |y_2| < 4.7$

These cuts allow us to compare our predictions with the first experimental data on azimuthal correlations of Mueller-Navelet jets at the LHC presented by the **CMS** collaboration (CMS-PAS-FSQ-12-002)

note: unlike experiments we have to set an upper cut on  $|\mathbf{k}_{J1}|$  and  $|\mathbf{k}_{J2}|$ . We have checked that our results don't depend on this cut significantly.

Azimuthal correlation  $\langle \cos \varphi \rangle$ 

$$\frac{c_1}{c_0} = \langle \cos \varphi \rangle \equiv \langle \cos(\phi_{J_1} - \phi_{J_2} - \pi) \rangle$$

The NLO corrections to the jet vertex lead to a large increase of the correlation

Azimuthal correlation  $\langle \cos \varphi \rangle$ 

$$\langle \cos \varphi \rangle \equiv \langle \cos(\phi_{J1} - \phi_{J2} - \pi) \rangle$$

$$35 \text{ GeV} < |\mathbf{k}_{J1}| < 60 \text{ GeV}$$

$$35 \text{ GeV} < |\mathbf{k}_{J2}| < 60 \text{ GeV}$$

$$0 < |y_1| < 4.7$$

$$0 < |y_2| < 4.7$$

- NLL BFKL predicts a too small decorrelation
- The NLL BFKL calculation is still rather dependent on the scales, especially the renormalization / factorization scale

Azimuthal correlation  $\langle \cos 2\varphi \rangle$ 

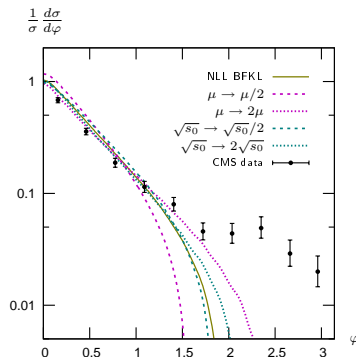

- The agreement with data is a little better for  $\langle \cos 2\varphi \rangle$  but still not very good
- This observable is also very sensitive to the scales

Azimuthal correlation  $\langle \cos 2\varphi \rangle / \langle \cos \varphi \rangle$ 

- This observable is more stable with respect to the scales than the previous ones
- The agreement with data is good across the full  $Y$  range

Azimuthal correlation  $\langle \cos 2\varphi \rangle / \langle \cos \varphi \rangle$ 

It is necessary to include the NLO corrections to the jet vertex to reproduce the behavior of the data at large  $Y$

Azimuthal distribution (integrated over  $6 < Y < 9.4$ )

- Our calculation predicts a too large value of  $\frac{1}{\sigma} \frac{d\sigma}{d\varphi}$  for  $\varphi \lesssim \frac{\pi}{2}$  and a too small value for  $\varphi \gtrsim \frac{\pi}{2}$
- It is not possible to describe the data even when varying the scales by a factor of 2

- The agreement of our calculation with the data for  $\langle \cos 2\varphi \rangle / \langle \cos \varphi \rangle$  is good and quite stable with respect to the scales
- The agreement for  $\langle \cos n\varphi \rangle$  and  $\frac{1}{\sigma} \frac{d\sigma}{d\varphi}$  is not very good and very sensitive to the choice of the renormalization scale  $\mu_R$
- An all-order calculation would be independent of the choice of  $\mu_R$ . This feature is lost if we truncate the perturbative series  
⇒ How to choose the renormalization scale?  
'Natural scale': sometimes the typical momenta in a loop diagram are different from the natural scale of the process

We decided to use the **Brodsky-Lepage-Mackenzie** (BLM) procedure to fix the renormalization scale

The **Brodsky-Lepage-Mackenzie** (BLM) procedure resums the self-energy corrections to the gluon propagator at one loop into the running coupling.

First attempts to apply BLM scale fixing to BFKL processes lead to problematic results. **Brodsky, Fadin, Kim, Lipatov and Pivovarov** suggested that one should first go to a physical renormalization scheme like MOM and then apply the 'traditional' BLM procedure, i.e. identify the  $\beta_0$  dependent part and choose  $\mu_R$  such that it vanishes.

We followed this prescription for the full amplitude at NLL.

Azimuthal correlation  $\langle \cos \varphi \rangle$ 

Using the BLM scale setting, the agreement with data becomes much better

Azimuthal correlation  $\langle \cos 2\varphi \rangle$ 

$$35 \text{ GeV} < |\mathbf{k}_{J1}| < 60 \text{ GeV}$$

$$35 \text{ GeV} < |\mathbf{k}_{J2}| < 60 \text{ GeV}$$

$$0 < |y_1| < 4.7$$

$$0 < |y_2| < 4.7$$

Using the BLM scale setting, the agreement with data becomes much better

Azimuthal correlation  $\langle \cos 2\varphi \rangle / \langle \cos \varphi \rangle$ 

Because it is much less dependent on the scales, the observable  $\langle \cos 2\varphi \rangle / \langle \cos \varphi \rangle$  is almost not affected by the BLM procedure and is still in good agreement with the data

Azimuthal distribution (integrated over  $6 < Y < 9.4$ )

With the BLM scale setting the azimuthal distribution is in good agreement with the data across the full  $\varphi$  range.

Using the BLM scale setting:

- The agreement  $\langle \cos n\varphi \rangle$  with the data becomes much better
- The agreement for  $\langle \cos 2\varphi \rangle / \langle \cos \varphi \rangle$  is still good and unchanged as this observable is weakly dependent on  $\mu_R$
- The azimuthal distribution is in much better agreement with the data

But the configuration chosen by CMS with  $\mathbf{k}_{J_{\min 1}} = \mathbf{k}_{J_{\min 2}}$  does not allow us to compare with a fixed-order  $\mathcal{O}(\alpha_s^3)$  treatment (i.e. without resummation)

These calculations are unstable when  $\mathbf{k}_{J_{\min 1}} = \mathbf{k}_{J_{\min 2}}$  because the cancellation of some divergencies is difficult to obtain numerically

In this section we choose the cuts as

- $35 \text{ GeV} < |\mathbf{k}_{J1}|, |\mathbf{k}_{J2}| < 60 \text{ GeV}$
- $50 \text{ GeV} < \text{Max}(|\mathbf{k}_{J1}|, |\mathbf{k}_{J2}|)$
- $0 < |y_1|, |y_2| < 4.7$

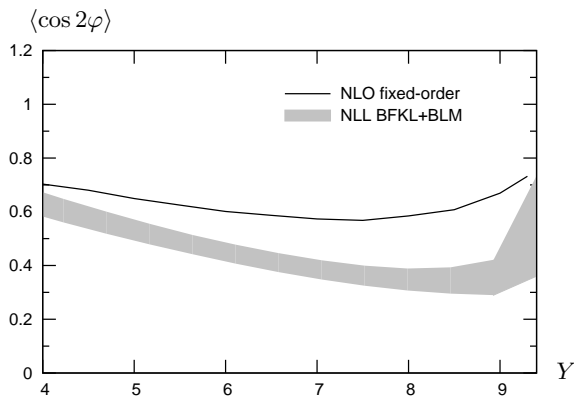

And we compare our results with the NLO fixed-order code Dijet ([Aurenche, Basu, Fontannaz](#)) in the same configuration

Azimuthal correlation  $\langle \cos \varphi \rangle$ 

$35 \text{ GeV} < |\mathbf{k}_{J1}| < 60 \text{ GeV}$   
 $35 \text{ GeV} < |\mathbf{k}_{J2}| < 60 \text{ GeV}$   
 $50 \text{ GeV} < \text{Max}(|\mathbf{k}_{J1}|, |\mathbf{k}_{J2}|)$   
 $0 < |y_1| < 4.7$   
 $0 < |y_2| < 4.7$

The NLO fixed-order and NLL BFKL+BLM calculations are very close

Azimuthal correlation  $\langle \cos 2\varphi \rangle$ 

$35 \text{ GeV} < |\mathbf{k}_{J1}| < 60 \text{ GeV}$   
 $35 \text{ GeV} < |\mathbf{k}_{J2}| < 60 \text{ GeV}$   
 $50 \text{ GeV} < \text{Max}(|\mathbf{k}_{J1}|, |\mathbf{k}_{J2}|)$

$0 < |y_1| < 4.7$   
 $0 < |y_2| < 4.7$

The BLM procedure leads to a sizable difference between NLO fixed-order and NLL BFKL+BLM

Azimuthal correlation  $\langle \cos 2\varphi \rangle / \langle \cos \varphi \rangle$ 

$35 \text{ GeV} < |\mathbf{k}_{J1}| < 60 \text{ GeV}$   
 $35 \text{ GeV} < |\mathbf{k}_{J2}| < 60 \text{ GeV}$   
 $50 \text{ GeV} < \text{Max}(|\mathbf{k}_{J1}|, |\mathbf{k}_{J2}|)$   
 $0 < |y_1| < 4.7$   
 $0 < |y_2| < 4.7$

Using BLM or not, there is a sizable difference between BFKL and fixed-order

## Cross section: 13 TeV vs. 7 TeV

$$35 \text{ GeV} < |\mathbf{k}_{J1}| < 60 \text{ GeV}$$

$$35 \text{ GeV} < |\mathbf{k}_{J2}| < 60 \text{ GeV}$$

$$50 \text{ GeV} < \text{Max}(|\mathbf{k}_{J1}|, |\mathbf{k}_{J2}|)$$

$$0 < |y_1| < 4.7$$

$$0 < |y_2| < 4.7$$

- In a BFKL treatment, a strong rise of the cross section with increasing energy is expected.
- This rise is faster than in a fixed-order treatment

It is necessary to have  $\mathbf{k}_{J_{\min 1}} \neq \mathbf{k}_{J_{\min 2}}$  for comparison with fixed order calculations but this can be problematic for BFKL because of energy-momentum conservation

There is no strict energy-momentum conservation in BFKL

This was studied at LO by [Del Duca and Schmidt](#). They introduced an effective rapidity  $Y_{\text{eff}}$  defined as

$$Y_{\text{eff}} \equiv Y \frac{\sigma^{2 \rightarrow 3}}{\sigma^{\text{BFKL}, \mathcal{O}(\alpha_s^3)}}$$

When one replaces  $Y$  by  $Y_{\text{eff}}$  in the expression of  $\sigma^{\text{BFKL}}$  and truncates to  $\mathcal{O}(\alpha_s^3)$ , the exact  $2 \rightarrow 3$  result is obtained

We follow the idea of Del Duca and Schmidt, adding the NLO jet vertex contribution:

exact  $2 \rightarrow 3$

BFKL

1 emission from the Green's function + LO jet vertex

we have to take into account these additional  $\mathcal{O}(\alpha_s^3)$  contributions:

no emission from the Green's function + NLO jet vertex

Variation of  $Y_{\text{eff}}/Y$  as a function of  $k_{J2}$  for fixed  $k_{J1} = 35$  GeV (with  $\sqrt{s} = 7$  TeV,  $Y = 8$ ):

- With the **LO** jet vertex,  $Y_{\text{eff}}$  is much smaller than  $Y$  when  $k_{J1}$  and  $k_{J2}$  are significantly different
- This is the region important for comparison with fixed order calculations
- The improvement coming from the **NLO** jet vertex is very large in this region
- For  $k_{J1} = 35$  GeV and  $k_{J2} = 50$  GeV, typical of the values we used for comparison with fixed order, we get  $\frac{Y_{\text{eff}}}{Y} \simeq 0.98$  at NLO vs.  $\sim 0.6$  at LO

- We studied Mueller-Navelet jets at full (vertex + Green's function) **NLL** accuracy and compared our results with the first data from the LHC
- The agreement with **CMS** data at 7 TeV is greatly improved by using the **BLM** scale fixing procedure
- $\langle \cos 2\varphi \rangle / \langle \cos \varphi \rangle$  is almost not affected by BLM and shows a clear difference between **NLO fixed-order** and **NLL BFKL** in an **asymmetric configuration**  
**Energy-momentum conservation** seems to be less severely violated with the NLO jet vertex
- We did the same analysis at 13 TeV:
  - Azimuthal decorrelations don't show a very different behavior at 13 TeV compared to 7 TeV
  - **NLL BFKL** predicts a stronger rise of the cross section with increasing energy than a **NLO fixed-order** calculation**A measurement of the cross section at  $\sqrt{s} = 7$  or 8 TeV would be needed to test this**

Dziękuję za uwagę !

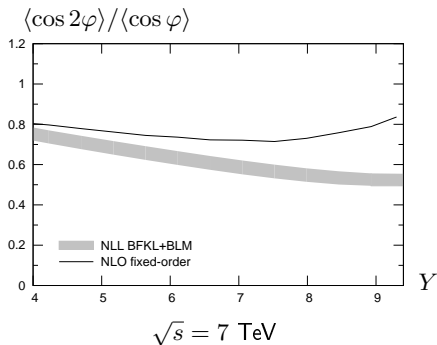

Azimuthal correlation  $\langle \cos \varphi \rangle$ 

The behavior is similar at 13 TeV and at 7 TeV

Azimuthal distribution (integrated over  $6 < Y < 9.4$ )

The behavior is similar at 13 TeV and at 7 TeV

Azimuthal correlation  $\langle \cos 2\varphi \rangle / \langle \cos \varphi \rangle$   
(asymmetric configuration)

The difference between BFKL and fixed-order is smaller at 13 TeV than at 7 TeV

## Cross section

It is useful to define the coefficients  $\mathcal{C}_n$  as

$$\mathcal{C}_n \equiv \int d\phi_{J1} d\phi_{J2} \cos(n(\phi_{J1} - \phi_{J2} - \pi)) \\ \times \int d^2\mathbf{k}_1 d^2\mathbf{k}_2 \Phi(\mathbf{k}_{J1}, x_{J1}, -\mathbf{k}_1) G(\mathbf{k}_1, \mathbf{k}_2, \hat{s}) \Phi(\mathbf{k}_{J2}, x_{J2}, \mathbf{k}_2)$$

- $n = 0 \implies$  differential cross-section

$$\mathcal{C}_0 = \frac{d\sigma}{d|\mathbf{k}_{J1}| d|\mathbf{k}_{J2}| dy_{J1} dy_{J2}}$$

- $n > 0 \implies$  azimuthal decorrelation

$$\frac{\mathcal{C}_n}{\mathcal{C}_0} = \langle \cos(n(\phi_{J,1} - \phi_{J,2} - \pi)) \rangle \equiv \langle \cos(n\varphi) \rangle$$

- sum over  $n \implies$  azimuthal distribution

$$\frac{1}{\sigma} \frac{d\sigma}{d\varphi} = \frac{1}{2\pi} \left\{ 1 + 2 \sum_{n=1}^{\infty} \cos(n\varphi) \langle \cos(n\varphi) \rangle \right\}$$
